Galy

Company Overview Galy is a US-based biotechnology startup that creates "Lab-Grown Cotton." Instead of growing entire plants in massive fields, they use plant cells to produce cotton fibers in a laboratory setting. This revolutionary technology aims to fix the high environmental cost of the global textile industry.

ESG Focus: Cellular Agriculture (Lab-Grown Fibers)

Why (The Problem) Traditional cotton farming is incredibly "thirsty" and "dirty." It takes about 2,700 liters of water to produce the cotton for just one T-shirt. Additionally, cotton farming uses a huge amount of pesticides and land, leading to soil exhaustion and habitat loss for animals.

How (The Solution) Galy uses a process called "Cellular Agriculture." They take a few cells from a cotton plant and grow them inside large bioreactors (similar to how beer is brewed). They provide the cells with the exact nutrients they need to multiply and turn into high-quality cotton fibers, without ever needing a farm.

What (The Outcome) This results in "Lab-Grown Cotton" that is identical to the cotton grown in a field but is produced 10 times faster. It uses 99% less water and 97% less land than traditional farming. Because it's grown in a controlled lab, there is no need for any pesticides or fertilizers.

Impact: Galy’s technology helps brands secure a stable supply of cotton that is not affected by climate change or droughts. By 2026, they aim to produce sustainable fibers at a large scale, significantly reducing the fashion industry's impact on the world's water supply.
