Kintra Fibers

Company Overview Kintra Fibers is a Brooklyn-based materials science company that creates bio-synthetic resins for the textile industry. They have designed a new type of polyester made from plants that solves the massive pollution problem associated with synthetic clothing.

ESG Focus: Bio-Synthetic Materials (Biodegradable Polyester)

Why (The Problem) Over 60% of our clothing is made from polyester, which is essentially plastic derived from crude oil. Every time we wash these clothes, they shed millions of "microfibers" into the water system. These microplastics end up in the ocean, harming marine life and entering the human food chain because traditional polyester never truly biodegrades.

How (The Solution) Kintra Fibers uses a proprietary resin made from 100% bio-based inputs (derived from plant sugars). They use these sugars to create a polymer that can be spun into yarn using standard polyester machinery. This allows major fashion brands to transition to sustainable fabrics seamlessly without changing their supply chains.

What (The Outcome) The result is a high-performance yarn that matches the strength, stretch, and softness of traditional polyester, but with a massive environmental upgrade. Kintra's fabric is designed to fully biodegrade in commercial composting environments, meaning it won't sit in landfills or oceans for centuries.

Impact: Kintra Fibers has received backing from major sustainable fashion funds and retail brands. Their innovation allows the apparel industry to keep the performance benefits of

synthetic athletic wear and outerwear while eliminating fossil fuel reliance and microplastic pollution.
